Below is a comprehensive test suite for Copy Propagation in pure JavaScript. Copy propagation replaces uses of a variable with the value of another variable when they are copies (e.g., x = y; … use x … → … use y …). These tests verify that copies are eliminated, that the original values are used directly, and that propagation does not happen when the source changes or when it would be illegal (e.g., across function calls that may modify the source).

```javascript
// ==============================================================================
// COMPREHENSIVE COPY PROPAGATION TEST SUITE (Pure JavaScript)
// ==============================================================================
// Run in any JavaScript engine that performs copy propagation.
// Tests verify that redundant copies are eliminated and values are propagated.

// ------------------------------------------------------------------------------

  console.error(`❌ ${totalTests - passed} tests failed.`);
}
```

How to use: Save as copy_propagation_tests.js and run in your JavaScript engine (Node.js, browser, or custom VM). The suite includes 30 test groups covering:

· Basic copy propagation and chains · Propagation across types (string, boolean, object, array) · Control flow (conditionals, loops, switch, try/catch) · Negative cases (intervening assignments, reassignments) · Function arguments, returns, closures, arrow functions · Destructuring, compound assignments, increment/decrement · Global variables, const, this, classes, symbols · Edge cases: eval, with, object property changes

All tests use runtime assertions and counters where needed to verify correct propagation behavior.
